Male Anatomy

Male Anatomy

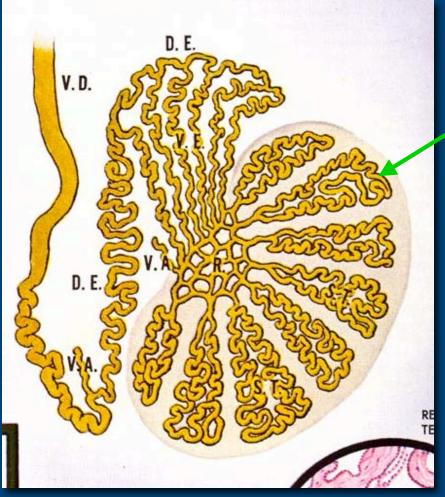

- Primary Organ
 - testes, genetically determined in mammals
 - testis releases hormones that then control the development of secondary sex characteristics
- Secondary Organs
 - internal duct system
 - e.g., vas deferens, epididymus
 - external genitalia
- Secondary Sexual Characters
 - e.g., antlers, coloration, facial hair

Eutherian Mammal Testes

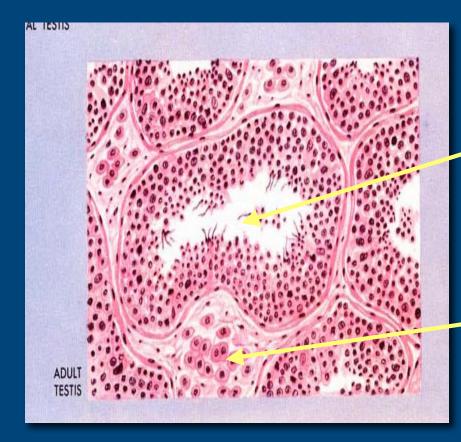

- Paired and oval shaped
- Shiny connective covering called the <u>Tunica Albuginea</u>
- Divided into <u>testicular</u>
 <u>lobules</u>
 - Approximately 250 in human testis

Seminiferous tubules (ST)

- Each testicular lobule contains several coiled
 <u>seminiferous tubules (ST)</u>
 - ST site of sperm production
- Each ST ~ 1.3 ft in humans
- Total length of ST almost the length of a football field

Testicular Histology

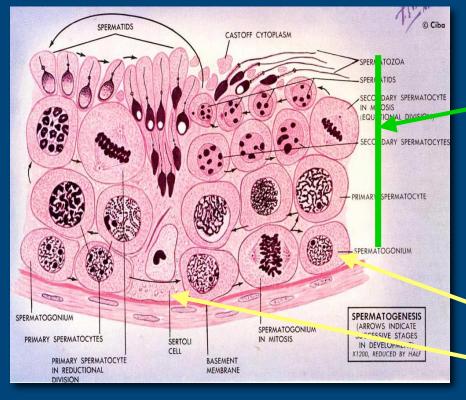

Testis is made up of 2 major compartments

1) Region inside seminiferous tubules Spermatozoa development

 2) Interstitial space outside ST

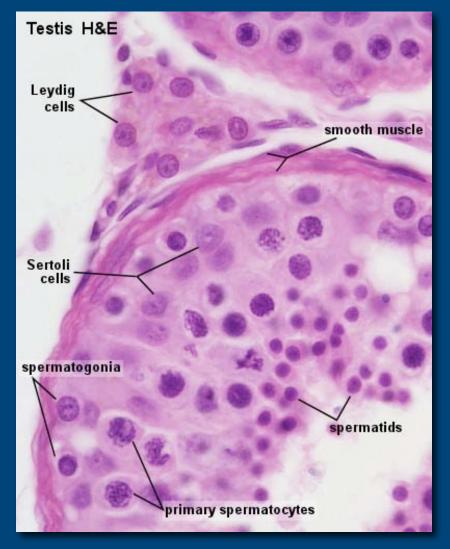

- Leydig cells,
- Androgen Production

Seminiferous Tubules

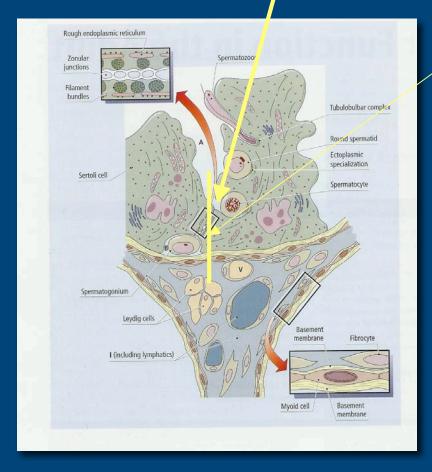

- Seminiferous tubules are lined by a <u>germinal</u>
 <u>epithelium</u>
- Primary product is spermatozoa
- Two cell types are found within ST
 - Germ cellsSertoli cells

Interstitial space

- Outside the ST
- Leydig cells
 - Responsible for androgen production in response to LH

Blood testis barrier

Limits fluid transfer between adluminal and basal and interstitial compartments

Prevents gametes entering interstitial space

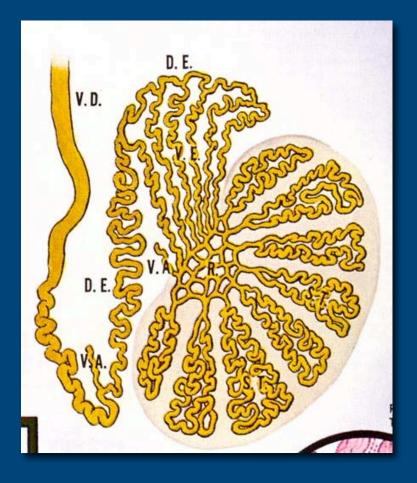

Blood testis barrier 2

- The two compartments are separated by a <u>blood testis barrier</u>
 - Consists of a series of <u>gap and tight junctions</u> that serve as a physiological barrier separating the sertoli cells from the capillaries located in the interstitial space.
 - Function: prevents immune response to "foreign" protein of gametes
 - Sperm granuloma

Ducts in males

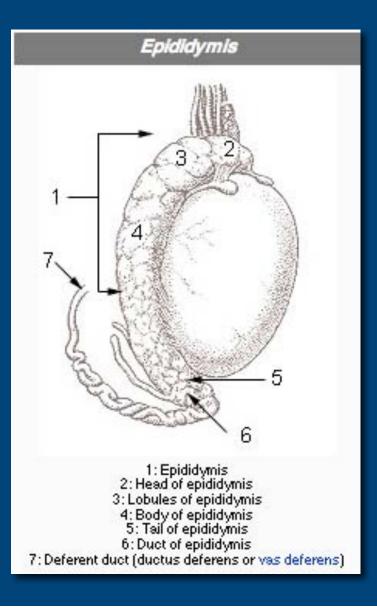

- All ducts in human <u>males</u> are derived from the primitive kidney
 - termed the **Wolffian ducts**
 - (or archinephric duct)

Ducts in males

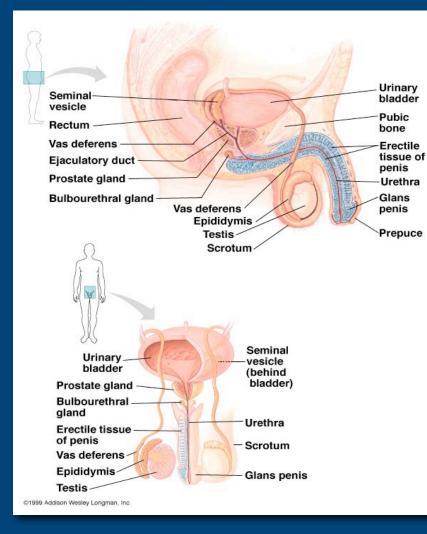

- 1) <u>Seminiferous tubules</u> –
- 2)**T<u>ubuli recti</u>** (straight tubules)
- 3) <u>Rete testis</u>- branched network of ducts
- 4) <u>Vasa efferentia</u>- carry to single common duct
- 5) <u>Epididymis</u>- single duct (>15 ft in human male)
- 6) <u>Vas deferens</u> pass out scrotum through inguinal canal to the urethra.

Epididymis

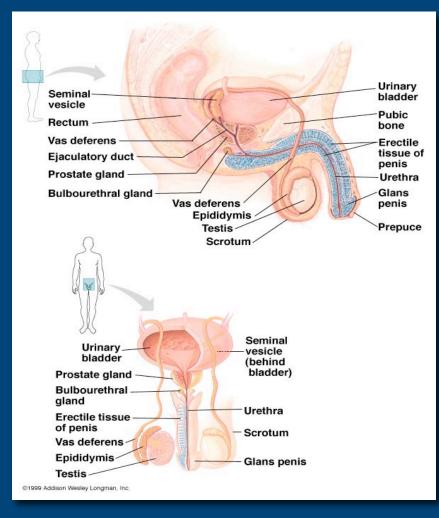

- Store sperm
- Maturation of sperm

Accessory Glands

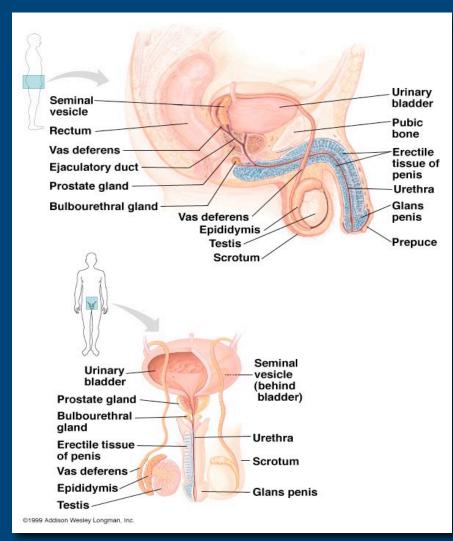

- Seminal Vessicles
- Prostate gland
- Bulbourethral glands
- Involved in the production of semen

Seminal Vesicles

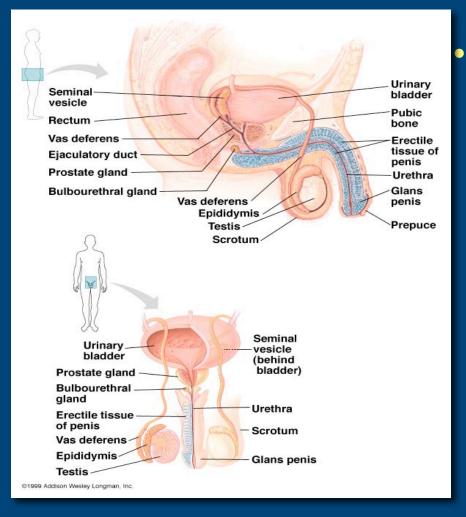

- Secrete alkaline, viscous fluid
- High fructose content
- Comprises the majority of semen

Prostate Gland

- Adds an alkaline solution to semen
- Facilitates a favorable environment for sperm in the more acidic vagina and female reproductive tract
- 13-33% of semen

Bulbourethral Glands

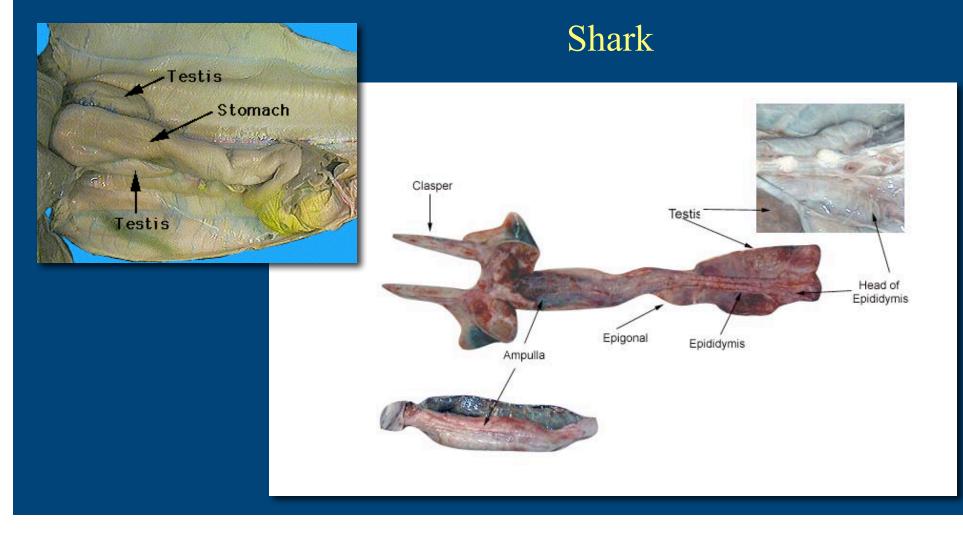

Secrete lubricant

Function of Ducts and Accessory Glands

- Sperm transport
- Sperm Storage
- Sperm maturation
- Production of semen

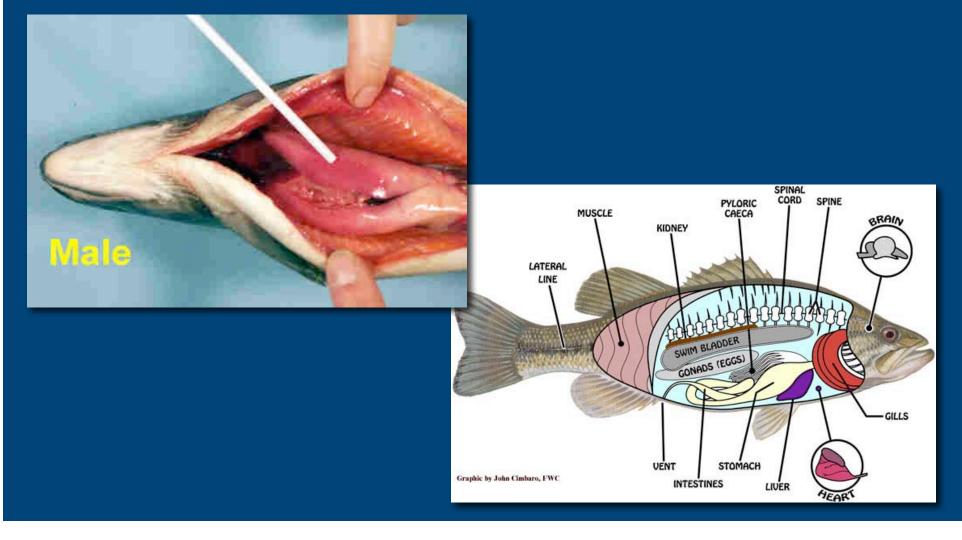

Comparative testis anatomy
Paired (embryologically) in all species

Can be fused

Comparative testis anatomy
Paired (embryologically) in all species

Can be fused

Birds - Ducts

- sperm leave testes and enter epididymis
 - very small in the bird
 - not divided into three parts like mammals
- then enter the ductus deferens
 - long narrow tube travels next to the ureter
 - ends at cloaca
- psittacines (parrots)
 - sperm storage in the ductus deferens
- passerines (finches, canaries, etc.)
 - sperm stored in the "seminal glomus"
 - convoluted structure at the end of the ductus
